

# The M-N Theorem

Ian Dardik

February 23, 2022

TODOS

1. Check cycle / cycle notation to make sure I'm saying it correctly.
2. Make sure the proof for the M-N theorem on the last few lines is clearer.
3. The proofs / language for the first 3 lemmas needs to be cleaned up.
4. Pin down Assumption 1.
5. Clean up preliminaries.
6. Write the intuition section.

## 1 Introduction

I begin with some preliminaries before introducing the M-N Theorem.

## 2 Preliminaries

Throughout this note we will consider a transition system  $T = (I, \Delta)$  parameterized by a single sort  $P$  with identical elements (i.e. each element is interchangeable for another).  $\Delta$  is the transition relation for  $T$  and we stipulate that it is in Prenex Normal Form (PNF).  $\Phi$  is an inductive invariant candidate that is also in PNF, and our goal is to determine whether or not  $\Phi$  is an inductive invariant for  $T$ .

Because  $\Phi$  and  $\Delta$  are in PNF, we can also refer directly to the matrices of these formulas as  $\phi$  and  $\delta$  respectively; i.e.  $\phi$  and  $\delta$  are propositional logic formulas parameterized by the variables that are quantified over in  $\Phi$  and  $\Delta$  respectively.

Because each element of  $P$  is interchangeable for another, we assume, without loss of generality, that  $P = \{1, \dots, |P|\}$ . In other words, for two sorts  $P$  and  $Q$ ,  $|P| < |Q| \leftrightarrow P \subset Q$ .

**Assumption 1.** Another detail on the assumption that  $P$ 's elements are identical: more precisely, let  $\alpha$  be a FOL formula parameterized by the variables in sort  $P$  (possibly with primes), and let  $g : P \rightarrow P$  be injective. Then:

$$\alpha \leftrightarrow \alpha[P \mapsto g(P)]$$

## 3 Finitely Instantiated Properties (FIPs)

In this section we introduce the FIP, a key tool for proving the M-N Theorem. We prove two basic lemmas about FIPs that will come in handy later.

### 3.1 FIP Basics

**Definition 1** (FIP). Let  $\Phi$  and  $\Delta$  be of two PNF formulas and let  $\phi$  and  $\delta$  be their respective matrices. Assume that  $\Phi$  quantifies over  $m \in \mathbb{N}$  variables while  $\Delta$  quantifies over  $n \in \mathbb{N}$  variables. Then a Finitely Instantiated Property (FIP) of  $[\Phi \wedge \Delta](|P|)$  is a formula  $(\phi \wedge \delta)[v_i \mapsto e_i]$ , where each free variable  $v_i$  has been substituted for a concrete element  $e_i \in P$ .

*Example 1.* Let  $\Phi = \forall p, q \in P, \phi(p, q)$  and  $\Delta = \exists p \in P, \delta(p)$ . Then  $\phi(1, 3) \wedge \delta(2)$  and  $\phi(1, 1) \wedge \delta(1)$  are both FIPs of  $[\Phi \wedge \Delta](3)$  (i.e. for the case when  $|P| = 3$ ).

*Remark 1.* We will often refer to  $\phi \wedge \delta$  without the substitution syntax for brevity. In these cases, we will explicitly refer to  $\phi \wedge \delta$  as a FIP, and not as a matrix.

**Definition 2** (Equivalent). Let  $\phi_1 \wedge \delta_1$  and  $\phi_2 \wedge \delta_2$  be FIPs, then  $\phi_1 \wedge \delta_1 \equiv \phi_2 \wedge \delta_2$  iff  $\phi_1 \wedge \delta_1$  is a permutation of  $\phi_2 \wedge \delta_2$ . In this case,  $\phi_1 \wedge \delta_1$  and  $\phi_2 \wedge \delta_2$  are said to be *equivalent*.

*Example 2.* Let  $F_1 = \phi_1(1, 2) \wedge \delta(1)$ ,  $F_2 = \phi_2(2, 3) \wedge \delta(2)$  and  $F_3 = \phi(2, 2) \wedge \delta(2)$  be FIPs of  $[\Phi \wedge \Delta](3)$ . Then  $F_1 \equiv F_2$  because  $F_1 (1\ 2\ 3) = F_2$  (using cycle notation). However  $F_3$  is a permutation of neither  $F_1$  nor  $F_2$  and hence is not equivalent to either.

*Remark 2.* FIP equivalency is commutative because permutations are commutative.

*Remark 3.* We specifically write a FIP of  $[\Phi \wedge \Delta](|P|)$  as “ $\phi \wedge \delta$ ” to show the syntactic correspondence of  $\phi$  to  $\Phi$  and  $\delta$  to  $\Delta$ . In other words, it is always the case that  $\phi = \text{RemoveMatrix}(\Phi)[v_i \mapsto e_i]$  and  $\delta = \text{RemoveMatrix}(\Delta)[v_i \mapsto e_i]$ .

**Lemma 1.** Let  $\phi_1 \wedge \delta_1$  and  $\phi_2 \wedge \delta_2$  both be FIPs of  $[\Phi \wedge \Delta](|P|)$ . Then:

$$((\phi_1 \wedge \delta_1) \equiv (\phi_2 \wedge \delta_2)) \rightarrow ((\phi_1 \equiv \phi_2) \wedge (\delta_1 \equiv \delta_2))$$

*Proof.* Suppose  $(\phi_1 \wedge \delta_1) \equiv (\phi_2 \wedge \delta_2)$ . Then there exists a cycle  $C$  such that  $(\phi_1 \wedge \delta_1) C = (\phi_2 \wedge \delta_2)$ , and equivalently  $(\phi_1 C) \wedge (\delta_1 C) = (\phi_2 \wedge \delta_2)$ . From Remark 3, we see that  $\phi_1$  and  $\phi_2$  are identical up to a finite instantiation, and hence  $\phi_1 C = \phi_2$ ; a similar argument shows that  $\delta_1 C = \delta_2$ .  $\square$

**Lemma 2.** Let  $\phi_1$  and  $\phi_2$  be quantifier-free properties parameterized by the sort  $P$ . Then:

$$(\phi_1 \equiv \phi_2) \leftrightarrow (\phi'_1 \equiv \phi'_2)$$

*Proof.* Suppose that  $\phi_1 \equiv \phi_2$ . Then there exists a cycle  $C$  such that  $\phi_1 C = \phi_2$ . Notice that the prime operator only affects state variables, and not parameters or their finite instantiations. Hence the prime operator does not affect the application of the cycle  $C$  and we have:

$$\phi'_2 = (\phi_1 C)' = (\phi'_1) C$$

Showing that  $\phi'_1 \equiv \phi'_2$  by definition. We omit the proof in the other direction since it is nearly identical.  $\square$

The notion of equivalency is important because it partitions a formula  $\Phi \wedge \Delta$  into distinct classes of FIPs. In the example above,  $F_1$  and  $F_2$  describe the same class of properties/actions because each element of  $P$  is interchangeable for one another. This leads us to the following lemma that is rather intuitive:

**Lemma 3.** Let  $\phi_1 \wedge \delta_1$  and  $\phi_2 \wedge \delta_2$  both be FIPs for  $\Phi \wedge \Delta$ . Suppose that  $\phi_1 \wedge \delta_1 \equiv \phi_2 \wedge \delta_2$ . Then:

$$(\phi_1 \wedge \delta_1) \leftrightarrow (\phi_2 \wedge \delta_2)$$

*Proof.* Because  $\phi_1 \wedge \delta_1 \equiv \phi_2 \wedge \delta_2$ , there exists a cycle  $C$  such that  $(\phi_1 \wedge \delta_1) C = \phi_2 \wedge \delta_2$ . However  $C$  is an injective map, and hence by Assumption 1:

$$\phi_1 \wedge \delta_1 \leftrightarrow (\phi_1 \wedge \delta_1)[P \mapsto C(P)] = \phi_2 \wedge \delta_2$$

$\square$

### 3.2 The FIPS Operator

In this section we introduce the FIPS operator:

**Definition 3.** Let  $\Phi$  and  $\Delta$  be PNF properties with respective matrices  $\phi$  and  $\delta$ . Suppose that  $\Phi$  quantifies over  $m \in \mathbb{N}$  variables while  $\Delta$  quantifies over  $n \in \mathbb{N}$  variables. Then:

$$\text{FIPS}(\Phi \wedge \Delta, |P|) := \{\phi(v_1, \dots, v_m) \wedge \delta(w_1, \dots, w_n) \mid v_1, \dots, v_m, w_1, \dots, w_n \in P\}$$

The FIPS operator simply contains every possible FIP for a given formula  $\Phi \wedge \Delta$ . Next, we prove this intuitive result:

**Lemma 4.**  $\text{FIPS}(\Phi \wedge \Delta, |P|) \subseteq \text{FIPS}(\Phi \wedge \Delta, |Q|) \leftrightarrow |P| \leq |Q|$

*Proof.* Recall that this time we assume  $|P| \leq |Q| \leftrightarrow P \subseteq Q$ . We begin by showing that  $|P| \leq |Q| \rightarrow \text{FIPS}(\Phi \wedge \Delta, |P|) \subseteq \text{FIPS}(\Phi \wedge \Delta, |Q|)$ :

$$\begin{aligned} \text{FIPS}(\Phi \wedge \Delta, |P|) &= \{\phi(v_1, \dots, v_m) \wedge \delta(w_1, \dots, w_n) \mid v_1, \dots, v_m, w_1, \dots, w_n \in P\} \\ &\subseteq \{\phi(v_1, \dots, v_m) \wedge \delta(w_1, \dots, w_n) \mid v_1, \dots, v_m, w_1, \dots, w_n \in Q\} \\ &= \text{FIPS}(\Phi \wedge \Delta, |Q|) \end{aligned}$$

Where the subset step follows from the fact that  $P \subseteq Q$ . Next we show that  $\text{FIPS}(\Phi \wedge \Delta, |P|) \subseteq \text{FIPS}(\Phi \wedge \Delta, |Q|) \rightarrow |P| \leq |Q|$ . Suppose that  $\text{FIPS}(\Phi \wedge \Delta, |P|) \subseteq \text{FIPS}(\Phi \wedge \Delta, |Q|)$ . Then we know that

$$\begin{aligned} &\{\phi(v_1, \dots, v_m) \wedge \delta(w_1, \dots, w_n) \mid v_1, \dots, v_m, w_1, \dots, w_n \in P\} \\ &\subseteq \{\phi(v_1, \dots, v_m) \wedge \delta(w_1, \dots, w_n) \mid v_1, \dots, v_m, w_1, \dots, w_n \in Q\} \end{aligned}$$

Which implies that  $P \subseteq Q$ , which in turn implies that  $|P| \leq |Q|$ . □

## 4 Intuition

We will build intuition by proving the M-N Theorem for small examples. Coming soon.

## 5 M-N Theorem

**Lemma 5** (FIP Saturation). Let  $\Phi$  and  $\Delta$  be formulas in PNF, where  $\Phi$  quantifies over  $m \in \mathbb{N}$  variables and  $\Delta$  quantifies over  $n \in \mathbb{N}$  variables. Then every FIP of  $[\Delta \wedge \Phi](k)$ , for  $k > m + n$ , has an equivalent FIP in  $[\Delta \wedge \Phi](m + n)$ .

*Proof.* Let  $k = |P| = m + n + z$  where  $z \in \mathbb{Z}_{>0}$  (recall that  $P = \{1, \dots, k\}$ ). Let  $\phi \wedge \delta$  be an arbitrary FIP of  $[\Phi \wedge \Delta](k)$ . Then, because  $[\Phi \wedge \Delta](k)$  quantifies over exactly  $m + n$  variables, there must be at least  $z$  elements in  $P$  that do not appear in  $\phi \wedge \delta$ . Let  $u \leq m + n$  be the number of elements of  $P$  that are used in  $\phi \wedge \delta$ , and let  $\{e_i\}_{i=1}^u$  be the subset of elements that are used. Consider the permutation using the following cycle notation:  $C = (e_1 \ 1) \dots (e_u \ u)$ . Notice that  $(\phi \wedge \delta) \circ C$  only uses elements  $1 \dots u$ . Since  $u \leq m + n$ , it must be the case that  $(\phi \wedge \delta) \circ C$  is a FIP of  $[\Phi \wedge \Delta](m + n)$ . □

**Theorem 1** (M-N). Let  $\Phi$  and  $\Delta$  be formulas in PNF, where  $\Phi$  quantifies over  $m \in \mathbb{N}$  variables and  $\Delta$  quantifies over  $n \in \mathbb{N}$  variables. Then  $\Phi$  is an inductive invariant for  $T(P)$  iff it is an inductive invariant for the finite instantiation  $T(m + n)$ .

*Proof.* It is clear that if  $\Phi$  is an inductive invariant, then it must be an inductive invariant for  $T(m+n)$ . We prove the opposite direction in the remainder of the proof.

In the case when the finite instantiation is less than  $m+n$ , the theorem follows by Lemma 4. We will focus on the case when the finite instantiation is larger than  $m+n$  for the remainder of the proof.

Suppose that  $\Phi(m+n) \wedge \Delta(m+n) \rightarrow \Phi(m+n)'$ . Let  $k > m+n$ , then we must show that  $\Phi(k) \wedge \Delta(k) \rightarrow \Phi(k)'$ . Consider an arbitrary FIP  $\phi \wedge \delta$  of  $[\Phi \wedge \Delta](k)$ . By Lemma 5, there exists a FIP  $\phi_2 \wedge \delta_2$  of  $[\Phi \wedge \Delta](m+n)$  such that  $\phi_2 \wedge \delta_2 \equiv \phi \wedge \delta$ . Now  $\phi_2 \wedge \delta_2$  holds by Lemma 3, which implies  $\phi'_2$ . By Lemma 1,  $\phi \equiv \phi_2$ , and by Lemma 2,  $\phi' \equiv \phi'_2$ . Finally, by Lemma 3, we can conclude that  $\phi'$  holds.  $\square$
